

Aethiomastacembelus traversi, a new spiny-eel from the Zaïre River basin, Africa (Synbranchiformes: Mastacembelidae)

Emmanuel J. Vreven* and Guy G. Teugels*,**

Aethiomastacembelus traversi, new species, is described from the lower and middle Zaïre basin, Africa. It is morphologically close to the *A. paucispinis* and the *A. conicus* species-complexes and is diagnosed by its long postanal length (54.5-60.0 % SL), its number of dorsal spines (20-22 + 1) and its unique coloration characterised mainly by its uniform brown colour on head and body and its black caudal fin. The generic assignment is discussed based on the most recent phylogenetic analysis of the family.

Introduction

The Mastacembelidae or spiny-eels are a group of freshwater fishes which for some time have been considered as belonging to the Perciformes but more recently have been assigned to the Synbranchiformes by Gosline (1983) and Travers (1984b). They are characterised by their slender and eel-like body, the presence of a peculiar rostral appendage and a series of separate spines along the dorsum in front of the soft dorsal fin. They occur in Africa, the Middle East and in South-East Asia.

As part of an ongoing revision of the alpha-level taxonomy of the African spiny-eels, we found five specimens, originating from the Zaïre River basin, that do not fit the description of any known mastacembelid species. A detailed morphological study led to the recognition of a new species; its description is given below.

Methods

Methods used follow Vreven & Teugels (1996). All measurements defined by Vreven & Teugels (1996) are point to point measurements except for the distance from the dorsal edge of the pectoral fin to the first dorsal spine, the distance from the ventral edge of the pectoral fin to the first dorsal spine, and the distance from the posterior edge of the pectoral fin to the first dorsal spine.

The preorbital distance of Travers (1992a-b) is identical to the snout length as defined by Vreven & Teugels (1996) (Fig. 1., nr. 1). The postorbital distance of Travers (Fig. 1., nr. 2) is different from the definition given by Vreven & Teugels (Fig. 1., nr. 3): in the former it is the distance from the posterior edge of the eye to the posterior margin of the cranium, visible externally as a groove above the top of the preopercular bone;

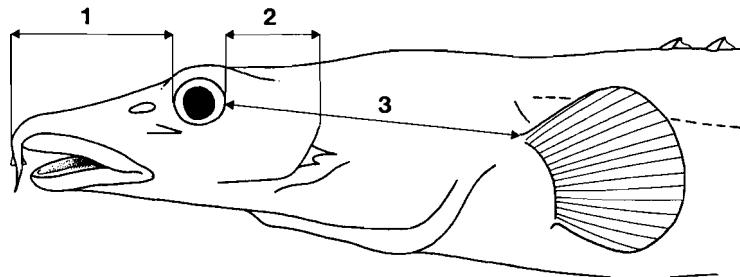

Fig. 1. Schematic illustration of the head of a mastacembelid fish, showing: 1, the preorbital distance of Travers (1992a-b) identical to the snout length of Vreven & Teugels (1996); 2, the postorbital distance of Travers (1992a-b); and 3, the postorbital distance of Vreven & Teugels (1996).

the latter, is defined as the distance from the posterior edge of the eye to the dorsal edge of the pectoral fin.

Aethiomastacembelus traversi, new species (Fig. 2)

Mastacembelus marchii (non Sauvage, 1879, in part)
(erroneous emendation): Poll, 1959: 111-112
(specimen MRAC 118575)

Holotype. MRAC 90-30-P-1951, 342 mm TL; Zaïre, Lualaba Riv., rapids, km 47 road Kisangani-Wanie Rukula; approx. 0°14'N 25°34'E; L. De Vos, 11 February 1990.

Paratypes. MRAC 118575, 160 mm TL (with mutilated tail); Zaïre, Stat. 37, Stanley-Pool, in front of Ile du Contrebandier; approx. 4°19'S 15°21'E; Mission Brien-Poll-Bouillon, 7 October 1957. – MRAC 73-22-P-5048, 376 mm TL; Zaïre, Stanley-Pool; approx. 4°06'S 15°15'E; J. Mandeville, 24 July 1958. – CAS-SU 66748, 337 mm TL; Zaïre, Kinshasa, Leopoldville market; approx. 4°18'S 15°18'E; T. R. Roberts, June-July 1964. – MCZ 148434, 192 mm TL; Central African Republic, Bangui fish market; approx. 4°22'N 18°35'E; T. R. Roberts, May 1971.

Diagnosis. *Aethiomastacembelus traversi* is distinguished from all other African mastacembelid species by the following combination of characters: postanal length (54.5-60.0 % SL) greater than preanal length (38.4-44.1 % SL); origin of first dorsal spine situated in front, above, or just behind posterior extremity of pectoral fin; 20+1 to 22+1 dorsal spines; a generally uniform body coloration except for the dorsal fin which has a rather dark brown base and a light yellowish distal margin with small brown spots, and for the caudal fin which is black.

Description. Measurements and counts for holotype and paratypes are given in Tables 1 and 2.

Aethiomastacembelus traversi has a pointed snout. Fleshy angle of jaws situated before or just below anterior border of the posterior nare. Upper extremity of gill opening and dorsal edge of pectoral-fin base at same level, anterior to ventral edge of pectoral-fin base. Upper part of pectoral fin base situated above upper extremity of gill opening; both clearly above ventral edge of pectoral-fin base. Upper jaw longer than lower jaw. Rostral appendage long (18.8-22.7 % HL).

Preanal length always shorter than postanal length. Distance from snout to posterior extremity of last dorsal spine (when flattened) less than distance from snout to posterior extremity of last anal spine (when flattened); distance from snout to base of first anal spine and preanal length longer than distance from snout to posterior extremity of last dorsal spine (when flattened).

20 to 22 externally visible dorsal spines, increasing in size from first to last. One very short spine hidden under the skin, and situated anteriorly to the base of the first soft ray.

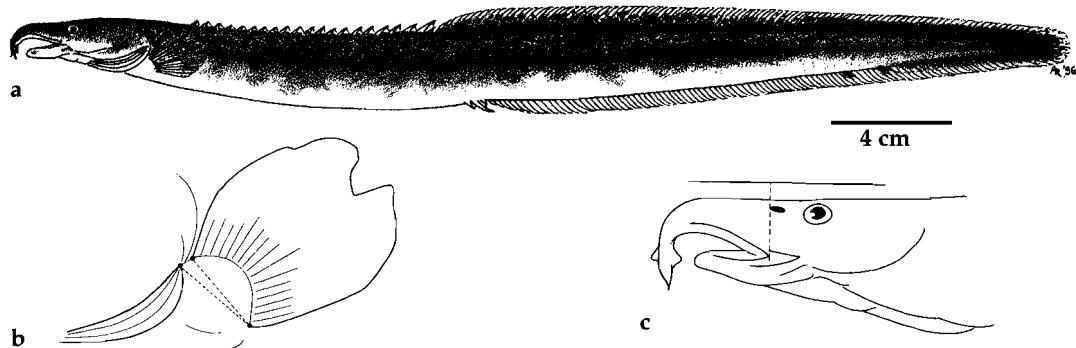

Fig. 2. *Aethiomastacembelus traversi*, MRAC 90-30-P-1951, holotype, 342 mm TL, Lualaba river. **a**, lateral view; **b**, detail of the gill opening region; note the anterior and distinctly superior position of the upper extremity of the gill opening compared to the ventral edge of the pectoral-fin base; **c**, position of the angle of the mouth, the posterior nostril and the eye.

Body depth at anus	7.3	7.0	7.8	8.0

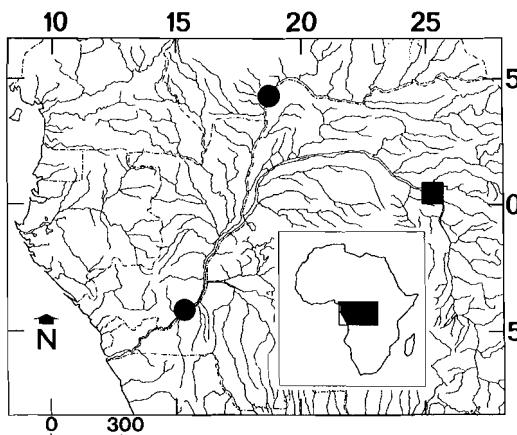

Fig. 3. Distribution of *Aethiomastacembelus traversi* based on the localities of the specimens examined, ■ type locality.

Two externally visible anal spines. One very short spine, hidden under the skin, and situated anteriorly to the base of the anal fin. First anal pterygiophore well developed, supporting first and second anal spine, and only pterygiophore supporting two spines.

In all specimens, the neural spine supporting the pterygiophore of the last externally visible dorsal spine and the haemal spine supporting the pterygiophore of the first anal spine are situated on two different vertebrae. The vertebra with the neural spine supporting the pterygiophore of the last externally visible spine is situated before the vertebra whose haemal spine supports the first anal spine.

All specimens have one preorbital spine, which may be hidden under the skin. Number of preopercular spines on left side 1 (in 1 specimen) or 2 (in 4 specimens) and 2 on the right side (in 5 specimens). The preopercular spines may also be hidden under the skin.

Coloration in alcohol. The coloration of most of the specimens is poorly preserved. Holotype with head and body uniformly colored, brownish dorsally and on sides, lighter yellowish on lips, lower cheek, lower side of head, belly, abdomen and ventral part of tail. Pectoral fins uniformly light yellowish. Dorsal fin, part of the confluent dorsal, caudal and anal fins rather uniformly dark brown at base. Outer margin light yellowish with small brown spots. Caudal fin black and anal fin uniformly light yellowish. No data on the life coloration are available.

Distribution. The specimens of *Aethiomastacembelus traversi* have been collected from the lower and middle Zaire River basin. The species is probably endemic to those parts of the Zaire River basin (Fig. 3).

Habitat. The holotype of *Aethiomastacembelus traversi* was collected from rapids on the Lualaba River, in a secondary forest area. Up and downstream of the rapids, the Lualaba is a large river (several hundred meters wide) and the next rapids downstream are those of Kisangani and upstream those of Wanie Rukula. More detailed information on the habitat and biology of the species are lacking.

Etymology. Named for Robert A. Travers who first tentatively recognised part of the type material as belonging to a new mastacembelid species.

Generic position and affinities. Vreven & Teugels (1996) discussed inaccuracies and contradictions in the diagnoses of *Caeconomastacembelus* Poll, 1958 and *Aethiomastacembelus* Travers, 1988 the two African genera recognised by Travers (1988, 1992a-b). Several of these diagnostic characters have no value for generic distinction because even the type species of the two genera do not exhibit the character state described for their genus (see Vreven & Teugels, 1996: table 5). For the remaining diagnostic characters the following character states were observed in *A. traversi* (data for both genera according to Travers, 1988, 1992a-b in parentheses): 11 principal caudal-fin rays (10-12 in *Aethiomastacembelus*; 8-10 in *Caeconomastacembelus*); snout pointed (tendency to have a pointed snout in *Aethiomastacembelus*; tendency to have a blunted snout in *Caeconomastacembelus*); body depth greatest midway along length (body depth greatest midway along length in *Aethiomastacembelus*; body depth even for most of length in *Caeconomastacembelus*) and dorsal fin deeper than anal fin (median fins of even height in *Aethiomastacembelus*; median fins low and fleshy, increase in height caudally in *Caeconomastacembelus*). Based on the character state of the remaining diagnostic characters mentioned above, we tentatively place *A. traversi* in *Aethiomastacembelus*.

Despite of the current confusion on the status of the genera and pending the results of an accurate generic revision of the African mastacembelids (Vreven, in prep.), we describe *A. traversi* here as a new species because it is clearly different from all other known African Mastacembelidae species.

The new species is morphologically close to *A. paucispinis* (Boulenger, 1899) (the 'representative' of the *paucispinis* complex) and *A. congicus* (Boulenger, 1896) (the 'representative' of the *congicus* complex) (both complexes defined by Travers, 1992a-b). *Aethiomastacembelus traversi* shows, but in a far less developed condition, the diagnostic characters of the *A. paucispinis* complex: a unique anterior development of the soft dorsal fin extending well beyond the origin of the soft anal fin, a reduction of the number of dorsal spines (6-9 + 1 dorsal spines in *A. paucispinis*) and an increased number of dorsal soft fin

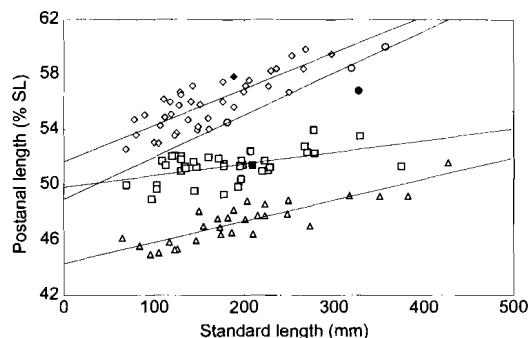

Fig. 4. Scatterplot of the postanal length (in % SL) against standard length for *Aethiomastacembelus traversi* (○), *A. congicus* (Δ), *A. paucispinis* (□) and *Caeconomastacembelus greshoffii* (◇). Full symbols refer to type specimens. Heavy lines are regression lines for *A. traversi*, *A. greshoffii*, *A. paucispinis* and *C. greshoffii*. The equations of the regression lines for the different species are: $y = 0.027x + 49.477$ for *A. traversi*; $y = 0.015x + 44.328$ for *A. congicus*; $y = 0.008x + 49.831$ for *A. paucispinis* and $y = 0.027x + 51.661$ for *A. greshoffii*.

rays (110-131 dorsal fin rays against 73-89 anal fin rays). This species-complex contains seven species (Travers, 1992a-b). Nevertheless, *A. traversi* can be distinguished from *A. paucispinis* by the elongation of its postanal region (see Fig. 4).

Further *A. traversi* possesses a narrow and tapered snout which is the diagnostic character of the *A. congicus* (Boulenger, 1896) complex. The snout length [preorbital distance of Travers (1992b)] is 1.5 times longer than the postorbital distance, as mentioned by Travers (1992b). The 11 species which were considered in this species-complex were not mentioned by Travers. However *A. traversi* can also be distinguished from *A. congicus* by the elongation of its postanal region (Fig. 4). As *A. traversi* exhibits the diagnostic characters of both complexes, their usefulness as presently defined can be questioned.

Caeconomastacembelus greshoffii (Boulenger, 1901) is the only other mastacembelid species, endemic to the Zaïre river basin, with a postanal length comparable to that in *A. traversi* (Fig. 4). *Aethiomastacembelus traversi* has fewer dorsal spines than *C. greshoffii* (20-22 + 1, vs. 29-33 + 1).
